

1 **METHOD FOR DRIVING LIQUID CRYSTAL DISPLAY DEVICES**

2 BACKGROUND OF THE INVENTION

3 1. Field of the Invention

4 The present invention relates to a method for driving liquid crystal
5 display (LCD) devices, in particular to a method of generating symmetrical
6 voltage signals to control with precision pixels displayed on a liquid crystal
7 display (LCD) device.

8 2. Description of Related Arts

9 With reference to Figs 11 and 12, pixels on an LCD device are arranged
10 in columns and rows with specific column addresses (S0, S1, etc.) and row
11 addresses (C0, C1, etc.). A particular pixel is activated by a voltage difference
12 (dV) between a column control signal (COM) and a row control signal (SEG).
13 The row control signal (SEG) in a conventional addressing technique does not
14 just target a pixel at a particular address (C0, S0), but all the other pixels in the
15 same row (S0) as well, because all the pixels in that row will receive the same
16 row control signal.

17 With reference to Fig. 12, this problem is overcome by selectively
18 applying four drive voltages (V0, V3, V4, V5) to the LCD display. The voltage
19 level of the column control signal (COM) is switched between V0 and V4, and
20 the voltage level of the row control signal (SEG) is switched between V3 and V5.
21 When one column of pixels is selected, the voltage level of the column control
22 signal (COM) is V0, and in the non-selection period, the voltage level is V4. The
23 row control signal (SEG) is switched between V3 and V5 depending on whether
24 the pixel status is 0 or 1. The maximum voltage level is V5. To improve the

performance, the drive voltage is generally boosted far beyond the operation voltage.

In actual operation, when a row of pixels is selected, the voltage difference of the individual pixels in the row is either $|V5-V0|$ or $|V3-V0|$ depending on whether the pixel status is zero or one. In the non-selection period, the voltage difference of all the pixels is either $|V5-V4|$ or $|V3-V4|$, which are the same (dV).

Since the performance of an LCD device is sensitive to DC bias voltage, the average voltage applied on each pixel has to be zero to remove the DC elements. To accomplish this, there needs to be six voltage levels, as shown in Fig. 13, for driving an LCD device. The voltage level of the column control signal (COM) has to be alternated between (V4, V0) and (V1, V5), and the row control signal (SEG) between (V3, V5) and (V2, V1), such that the average voltage value applied on each pixel can be kept at zero $\Sigma V_{\text{pixel}}=0$, whilst the voltage difference for each pixel $|V_{\text{pixel}}|$ remains unchanged. Therefore the above operation shall satisfy the following conditions to produce a constant dV value: $V5-V4=V4-V3=V2-V1=V1-V0=dV$.

A conventional method of applying six voltage levels is shown in Fig. 14. In this implementation, a plurality of series resistors is used for voltage division. The voltage levels are controlled by the resistance in the series resistors. Since this method of selecting the resistance value is not precise, in that case, the above-mentioned conditions cannot be achieved. The resistance value in a factory-produced resistor device is usually not precisely set, but rather with a tolerance margin. Normally, a substantial drive current is needed to offset noise

1 disturbance in the circuit, which is a power-consuming method. If several voltage
2 differences (dV) are needed on the same chip, it is necessary to hardwire resistors
3 in different sections of the circuit manually. Therefore, the precision of the
4 voltage settings is largely questionable during circuit action.

5 Another conventional way of generating voltage levels is shown in Fig.
6 15, by utilizing a voltage doubling circuit. This design is based on the assumption
7 that $V_0=0$, where both V_1 and V_2 are generated by the operation voltage (V_{dd})
8 and $V_2 = 2V_1$. The shortcoming is that V_1 and V_2 cannot be larger than the
9 operation voltage (V_{dd}). A voltage doubling circuit, a multiple of the original
10 input voltage (V_1), generates the voltage levels (V_2 , V_3 , and V_5). If the required
11 voltage difference (dV) between V_5 and V_1 is other than a round number
12 multiple, then the circuit modification can be very complicated. Furthermore,
13 since V_5 is the high voltage supplying the entire circuit, the current output of the
14 circuit will be lessened most of the time, thus the above-mentioned conditions are
15 not likely to be achieved.

16 SUMMARY OF THE INVENTION

17 The main object of the present invention is to provide a method for
18 driving liquid crystal display (LCD) devices, such that the drive voltage can be
19 precisely set with a constant voltage difference (dV) for precision control of the
20 pixel display on an LCD device.

21 The control technique calls for the creation of $N+1$ voltage levels ($V_0 \sim V$
22 $_N$), comprising the steps of :

23 defining a minimum voltage level serving as the base voltage (V_0);

24 defining a maximum voltage level serving as the high voltage (V_N);

1 defining all voltage levels to-be-established ($V_1 \sim V_{N-1}$) other than the
2 high voltage (V_N) and the base voltage (V_0);

3 establishing any voltage level among all voltage levels to-be-established
4 ($V_1 \sim V_{N-1}$) basing on the high voltage (V_N), and then defining the new voltage
5 level as an established voltage level;

6 establishing any voltage level still not established among voltage levels
7 to-be-established ($V_1 \sim V_{N-1}$) basing on the base voltage (V_0), high voltage (V_N),
8 and all established voltage levels, and then defining the new voltage level as an
9 established voltage level.

10 The present invention is characterized in that the established voltage is
11 always used as a base voltage for establishing the next voltage among voltage
12 levels to-be-established ($V_1 \sim V_{N-1}$).

13 The present invention is characterized in that the voltage difference dV
14 between any two adjacent voltage levels is always a constant value, from the base
15 voltage to the $\frac{N+1}{2} - 1$ th voltage level, and from $\frac{N+1}{2}$ th voltage level to the
16 high voltage (V_N).

17 Since each voltage level is established from the immediately preceding
18 voltage level, if any previously established voltage is changed, then all
19 subsequently generated voltage levels will be affected by the change and adjusted
20 accordingly, to maintain the constant voltage difference value dV between two
21 adjacent voltage levels.

22 The features and structure of the present invention will be more clearly
23 understood when taken in conjunction with the accompanying drawings.

1 BRIEF DESCRIPTION OF THE DRAWINGS

4 voltage levels.

5 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

6 The present invention provides a method for driving liquid crystal
7 display (LCD) devices involving the generation of $N+1$ levels of drive voltage
8 ($V_0 \sim V_N$) for precision control of pixel display on a LCD device. This voltage
9 control technique includes the steps of:

10 defining a minimum voltage level serving as a base voltage (V_0);
11 defining a maximum voltage level serving as a high voltage (V_N);
12 defining all voltage levels among voltage levels to-be-established ($V_1 \sim V_{N-1}$) other than the high voltage (V_N) and the base voltage (V_0);

14 establishing any voltage level among voltage levels to-be-established
15 ($V_1 \sim V_{N-1}$) basing on the high voltage (V_N), and then defining the new voltage
16 level as an established voltage level;

17 establishing any voltage level still among voltage levels to-be-
18 established ($V_1 \sim V_{N-1}$) basing on the base voltage (V_0), the high voltage (V_N), and
19 all previously established voltage levels, and then defining the new voltage level
20 as an established voltage level; wherein,

21 the established voltage level is always used as the base voltage for
22 establishing the next voltage in voltage levels to-be-established ($V_1 \sim V_{N-1}$).

23 The voltage difference dV between any two adjacent voltage levels is
24 always a constant value, from the base voltage to the $\frac{N+1}{2}-1$ th voltage level,

1 and from $\frac{N+1}{2}$ th voltage level to the high voltage (V_N).

2 To illustrate with an actual example, the basic hardware for the first
3 preferred embodiment, as shown in Fig. 1, incorporates a first stage circuit (10)
4 as a division circuit, a second stage circuit (20) as a division circuit, a third stage
5 circuit (30) as a subtraction circuit, and a fourth stage circuit (40) as a subtraction
6 circuit. Six voltage levels ($V_0 \sim V_5$), $N+1=6$, are defined for the drive voltage,
7 as depicted in Fig. 2.

8 For simplicity in the present discussion, the base voltage (V_0) is assumed
9 to be zero value. The main point is that each voltage level is related to any other
10 among the six voltage levels ($V_0 \sim V_5$). Therefore if any voltage is changed, then
11 all other voltage levels have to be changed, so as to maintain the constant dV
12 between any adjacent voltage levels ($V_0 \sim V_5$).

13 The generation of all six voltage levels is shown in Fig. 3. The high
14 voltage (V_5) is first input into the first stage circuit (10) to generate a second
15 voltage (V_2), and then the second voltage (V_2) is input into the second stage
16 circuit (20) (a division circuit), dividing by two, to obtain the first voltage (V_1),
17 and then the fourth voltage (V_4) and the third voltage (V_3) are respectively
18 derived from preceding voltages through the third and fourth stage circuits (30,
19 40).

20 The fourth voltage (V_4) is generated through the third stage circuit (30),
21 by subtracting the first voltage (V_1) from the high voltage (V_5); the third voltage
22 (V_3) is generated through the fourth stage circuit (40), by subtracting the second
23 voltage (V_2) from the high voltage (V_5). However, the voltage difference (dV)

1 between the second voltage (V2) and the third voltage (V3) is adjustable.

2 From the above description, it is apparent that the generation of voltage
3 levels follows this sequence: $V2 \rightarrow V1 \rightarrow V4 \rightarrow V3$. If any established voltage
4 level (for example, V2 or V1) is changed, all voltage levels derived therefrom
5 (for example, V4 or V3) have to be changed to maintain the constant voltage
6 difference (dV).

7 The original implementation shown Fig. 1 can be changed by capacitor
8 switching to create the first to fourth stage circuits(10~40), as implemented in the
9 second preferred embodiment in Fig. 3. The outputs of the first to fourth stage
10 circuits (10~40) are connected to a buffer (50) to boost the driving capability of
11 the output voltage. The main advantage of using capacitor switching is the
12 realization of power saving.

13 The architecture of the first to fourth stage circuits (10~40) is shown in
14 Figs. 4~6, wherein the third and fourth stage circuits (30) are identical to those
15 used in the previous example, other than that the input voltage in this case
16 becomes the first voltage (V1) or the second voltage (V2), and a switch is used
17 for switching among the first to fourth stage circuits (10~40), individually
18 controlled by clock signals (P1~P3) as shown in Fig. 7. The first stage circuit, in
19 Fig. 4, is a division circuit. The output of the second voltage (V2) can be
20 expressed as $V2 = V5 \times C1 / (C1 + C2)$. The circuit shown in Fig. 5 is also a division
21 circuit, but two capacitors of equal capacitance act as a divide-by-two circuit to
22 generate the first voltage (V1), which can be expressed as
23 $V1 = V2 / 2 = V2 \times C3 / (C3 + C3)$. The circuit shown in Fig. 6 is a subtraction circuit,
24 generating the third voltage (V3), which can be expressed as $V3 = V5 -$

1 $V2 \text{ or } V4 = V5 - V1$.

2 Three more variations of the present invention are shown in Figs. 8-10.

3 In each case, the first stage circuit (10) still uses the high voltage ($V5$) as an input
4 for generating the first, third and fourth voltages ($V1$, $V3$, and $V4$). The second,
5 third and fourth stage circuits (20~40), in working with the first stage circuit (10),
6 can be set up as a multiplication circuit, a division circuit and a subtraction
7 circuit.

8 If the high voltage ($V5$) and the base voltage ($V0$) are fixed values, the
9 value of voltage difference (dV) has to be changed to dV' for reasons of
10 controlling the drive voltage, and it is only necessary to change the first stage
11 circuit (10) to have all voltage levels readjusted again for normal operation.

12 Using the first embodiment in Fig. 1 as an example, if the output voltage
13 of the second stage circuit (20) is $V2'$, and $V0 = 0$, the first voltage ($V1'$) is
14 exactly half of the second voltage ($V2'$). Therefore, the second stage circuit (20)
15 is still a divide-by-two circuit, to generate a new first voltage $V1'$ that is only half
16 of the new second voltage $V2'$. The voltage difference between the new first
17 voltage $V1'$ and the base voltage $V0$ is set to be dV' , and the new third and fourth
18 voltages ($V4'$, $V3'$) are to be derived from the new first and second voltages ($V1'$,
19 $V2'$), and the voltage differences are changed to dV' .

20 This method of changing the first stage circuit (10) is not only applicable
21 to the first embodiment, but also to the other three embodiments shown in Figs.
22 8~10.

23 In summary, the method for driving liquid crystal display devices is to
24 use the voltage level of an existing voltage level as the base voltage and all other

1 voltage levels are to be derived therefrom. If any established voltage is changed,
2 then all subsequently established voltage levels also have to be changed to
3 maintain the constant voltage difference value (dV). If for reasons of controlling
4 the drive voltage, the voltage difference (dV) is changed, it is only necessary to
5 modify the first stage circuit, so that all following circuits will be changed
6 simultaneously to match the new dV.

7 The foregoing description of the preferred embodiments of the present
8 invention is intended to be illustrative only and, under no circumstances, should
9 the scope of the present invention be so restricted.
